

## Divided differences for a function $f(x)$

The divided differences are defined recursively as:

$$f[x_i] = f(x_i) \tag{1}$$

$$f[x_{i-1}, x_i] = \frac{f[x_i] - f[x_{i-1}]}{x_i - x_{i-1}} \tag{2}$$

$$f[x_{i-2}, x_{i-1}, x_i] = \frac{f[x_{i-1}, x_i] - f[x_{i-2}, x_{i-1}]}{x_i - x_{i-2}} \tag{3}$$

$\vdots$

$$f[x_{i-j}, x_{i-j+1}, \dots, x_i] = \frac{f[x_{i-j+1}, x_{i-j+2}, \dots, x_i] - f[x_{i-j}, x_{i-j+1}, \dots, x_{i-1}]}{x_i - x_{i-j}}. \tag{4}$$

$x_i$	$f[x_i]$	$f[x_{i-1}, x_i]$	$f[x_{i-2}, x_{i-1}, x_i]$	$\dots$	$f[x_{i-j}, x_{i-j+1}, \dots, x_i]$
$x_0$	$f[x_0]$				
$x_1$	$f[x_1]$	$f[x_0, x_1]$			
$x_2$	$f[x_2]$	$f[x_1, x_2]$	$f[x_0, x_1, x_2]$		
$x_3$	$f[x_3]$	$f[x_2, x_3]$	$f[x_1, x_2, x_3]$		
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	
$x_j$	$f[x_j]$	$f[x_{j-1}, x_j]$	$f[x_{j-2}, x_{j-1}, x_j]$	$\dots$	$f[x_0, x_1, \dots, x_j]$

Table 1: Divided differences table.

## Newton Interpolation

*Newton Interpolation* is one of the polynomial methods used for the interpolation of a data set of points. It uses divided differences.

We consider known a set of  $n + 1$  points  $(x_i, y_i)$ ,  $i = 0, 1, 2, \dots, n$ :

$$\begin{array}{ll}
 x_0 & y_0 = f(x_0) \\
 \vee & \\
 x_1 & y_1 = f(x_1) \\
 \vee & \\
 x_2 & y_2 = f(x_2) \\
 \vee & \\
 \vdots & \vdots \\
 \vee & \\
 x_n & y_n = f(x_n),
 \end{array} \tag{5}$$

but not the analytic expression of the function  $f(x)$ . The goal is to estimate  $f(x)$  at an arbitrary  $x$  using smooth curves through and beyond all  $x_i$ , for  $i = 0, 1, 2, \dots, n$ . By *interpolation*, we understand the estimation of  $f(x)$  for any  $x \in [x_0, x_n]$ . The *extrapolation* is the estimation of  $f(x)$  for  $x \in (-\infty, x_0] \cup [x_n, \infty)$ .<sup>1</sup>

The *order of interpolation* is given by the number of points used in the interpolation scheme minus one, i.e.  $n + 1 - 1 = n$ .

The Newton interpolation is based on the Newton polynomial approximation that can be derived like an expansion, but based on multiple centers  $(x_0, x_1, \dots, x_n)$ .

### Theorem (Newton polynomial)

Assume  $f \in C^{n+1}[a, b]$  and the set of  $n + 1$  distinct points

$$(x_i, y_i), \quad i = 0, 1, 2, \dots, n, \quad \text{with } x_i \in [a, b] \text{ and } y_i = f(x_i). \quad (6)$$

Then  $f(x)$  can be written as

$$f(x) = P_n(x) + R_n(x),$$

where  $P_n(x)$  is a polynomial of degree  $n$  that can be used to approximate  $f(x)$  and is given by

$$P_n(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)(x - x_1) + \dots + a_n(x - x_0)(x - x_1) \dots (x - x_{n-1}). \quad (7)$$

The coefficients  $a_i$ ,  $i = 0, 1, 2, \dots, n$  are constructed using divided differences.

As  $f(x) \approx P_n(x)$ , we have for the given set of points:

$$y_i = f(x_i) = P_n(x_i) \quad (8)$$

and the polynomial goes through the  $n + 1$  points  $(x_i, y_i)$ ,  $i = 0, 1, 2, \dots, n$ .

The remainder is given by

$$R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!} (x - x_0)(x - x_1) \dots (x - x_n),$$

for  $c$  a value in the interval  $[a, b]$ .

The coefficient  $a_i$  of the Newton polynomial (7) is

$$a_i = f[x_0, x_1, \dots, x_i], \quad (9)$$

i.e. the most to the right element on the row corresponding to the current  $x_i$  in table 1.

For convenience, let us denote

$$d_{i,j} = f[x_{i-j}, x_{i-j+1}, \dots, x_i]. \quad (10)$$

Then

$$d_{i,0} = f[x_i], \quad i = 0, 1, \dots, n \quad (11)$$

$$d_{i,j} = \frac{d_{i,j-1} - d_{i-1,j-1}}{x_i - x_{i-j}}, \quad \begin{matrix} i = 1, 2, \dots, n \\ j = 1, 2, \dots, i. \end{matrix} \quad (12)$$

---

<sup>1</sup>Note that interpolation and extrapolation differ from function approximation. For the first two  $f(x_i)$  is not given at points on our choice, while in the function approximation one tries to find an approximate easy to compute function.

With the above notations, the Newton polynomial is

$$P_n(x) = d_{0,0} + d_{1,1}(x - x_0) + d_{2,2}(x - x_0)(x - x_1) + \cdots + d_{n,n}(x - x_0)(x - x_1) \cdots (x - x_{n-1}). \quad (13)$$

and can be created recursively:

$$P_0(x) = d_{0,0} \quad (14)$$

$$P_1(x) = P_0(x) + d_{1,1}(x - x_0) \quad (15)$$

$$P_2(x) = P_1(x) + d_{2,2}(x - x_0)(x - x_1) \quad (16)$$

⋮

$$P_n(x) = P_{n-1}(x) + d_{n,n} \prod_{i=1}^{n-1} (x - x_i). \quad (17)$$

## Algorithm

- Give the list of points:<sup>2</sup>

$$\{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}. \quad (18)$$

- Calculate the divided differences using the known values  $y_i = f(x_i)$ .

- For  $i = 1, 2, \dots, n$ ,  $d_{i,1} = y_i$ .

- For  $i = 1, 2, \dots, n - 1$ , and for  $j = 1, 2, \dots, i$ ,

$$d_{i+1,j+1} = \frac{d_{i+1,j} - d_{i,j}}{x_{i+1} - x_{i-j+1}}. \quad (19)$$

- Calculate the Newton polynomial of degree  $n - 1$ :

$$P(x) = d_{1,1} + \sum_{i=1}^{n-1} \left( d_{i+1,i+1} \prod_{j=1}^i (x - x_j) \right) \quad \text{or} \quad P(x) = d_{1,1} + \sum_{i=2}^n \left( d_{i,i} \prod_{j=1}^{i-1} (x - x_j) \right). \quad (20)$$

---

<sup>2</sup>In order to implement the set of points as a Mathematica list, we start with  $(x_1, y_1)$  instead of  $(x_0, y_0)$ , having thus  $n$  points instead of  $n + 1$ .
